

1. Resolving Page Freezing or Unresponsive Interface

1. Do not repeatedly click buttons or submit forms if the screen freezes, as this may queue multiple conflicting requests to the server.
2. Force-refresh the browser by pressing **Ctrl + F5** (Windows) or **Cmd + Shift + R** (Mac) to clear the local page cache and reload fresh scripts.
3. If the page remains frozen, check the browser's memory usage. Close inactive browser tabs or external applications to free up system RAM.
4. If accessing the system via a local offline node, verify that the background C# backend terminal (Port 5268) has not crashed, paused, or entered "Select" mode (press Escape in the terminal if it is paused).

2. Troubleshooting High Latency or Lagging Dashboard

1. Check the real-time latency metric in the Telemetry Logs table.
2. If the latency consistently exceeds 15,000 ms, check your physical network connection. Disconnect and reconnect to the primary factory Wi-Fi subnet.
3. Open the **Admin Dashboard** and review the "Total Queries" chart. A sudden massive spike may indicate a system bottleneck or Denial of Service (DoS) anomaly.
4. Clear your browser cookies and cached site data for the IPMS domain.
5. If the lag persists across multiple devices, escalate the issue to the IT department to perform a rolling restart of the backend API and database services.

3. Dashboard Data Not Loading (Blank Charts or Tables)

1. Press **F12** to open the browser's Developer Tools and navigate to the "Console" or "Network" tab to check for red "Failed to fetch" connection errors.
2. Verify that the backend API node is actively running and broadcasting on the correct designated port.
3. Ensure you have the correct administrative privileges, as some telemetry data and logs are intentionally hidden from standard operator roles.
4. Log out of the IPMS portal completely and log back in to refresh your secure session authentication token.
